

(a)

Morra Each computing server plays  $\eta_h$ rounds of Morra to generate public

Coins

Public

(b)

Based on the public randomness, the servers are instructed to adjust their private values and then aggregate the vectors and broadcast.

Each server samples  $\eta_h$  copies of  $\overrightarrow{v}_i \in \mathbb{Z}_q^M$  and commits to  $\overrightarrow{v}_i$  using private randomness  $\vec{r}_i$ . An honest server samples  $\overrightarrow{v}_i \in \{0,1\}^M$ 

 $\overrightarrow{v}_{i}$ 

randomness  $\overrightarrow{b}_1, ..., \overrightarrow{b}_{\eta_b}$ . Morra is secure with abort in presence of a

dishonest majority.
